

g++ -c functions.cpp

← "object file"

functions.o

g++ -c swap.cpp

swap.o

g++ functions.o swap.o

a.out ← runnable program at last.

Reminder + pictures for reference vs value parameters.

```
int f(int x)
```

```
{  
    ...  
} // Note: x is by value
```

```
int g(int &y)
```

```
{  
    ...  
} // Note: y is by reference
```

```
int main()
```

```
{  
    int a = 3, b = 11;
```

```
    f(a);
```

```
    g(b);
```

```
    ;  
}
```

main memory

As you can see, whatever happens to y inside of g() will also happen to b inside main().
